TECH DATA

Version

2.2.0

Summary of Changes

This section highlights the details of changes made since the previous issue of this document.

The versioning convention used to track changes in this document follows the structure Vx.y.z where:

x: Major revision, where extensive changes are made which is generally incompatible with the previous version. Such changes may include new products and/or features, or removal of information which is no longer relevant or applicable to the previous version

y: Minor revision, where changes made do not change the overall scope of the previous version, but may include additional information which complements or corrects the previous version, or provides additional clarity on an existing topic.

z: Patch version, where small changes are made to correct minor errors or adjust existing text, charts, figures and/or images, and which do not add or remove information from the previous version. Example changes may include spelling corrections, image re-sizing and adjustments, updated images, etc.

Version	Publication date	Changes	By
V 1.0.0	29-Apr-2021	Initial release	N.ALEX
V 1.1.0	10-June-2021	Corrections to Part Number Break Down, typo fixes and further verified combinations, clarified that quoted selectivity values are based on I_n	N.ALEX
V 1.2.0	27-Sept-2021	Added ZS Cascading and Selectivity, added ACB to MCCB Selectivity, fixed typo on Part Number Break Down, corrections/additions to Available MCCBs, corrections to A250F available trip units, added more explanations around selectivity and how the tables are to be used.	N.ALEX
V 1.2.1	28-Sept-2021	Typo and spelling corrections	N.ALEX
V 2.0.0	07-March-2022	Reformatted tables, layout, headings, document flow, Added A250_200TM columns, Added DSRCBT, M6RCBT, M6RCBF., Added refers to DSRCM results being based on the MCB its mounted to, Concept Isolator Selectivity tables added.	N.ALEX
V 2.0.1	30-March-2022	Fixed typo on Concept Isolator with DTCTB15	N.ALEX
V 2.1.0	11-May-2023	Fixed typo in headings, Added Publication of responsibility, removed Terasaki global offering breaker	N.ALEX
V 2.2.0	08-April-2024	Revised cascading for M6RCBT & DSRCBT	N.ALEX

Publication of responsibility

The contents of this document have been reviewed to ensure that the reliability of the information is correct at time of publication.

NHP or Terasaki are not responsible for printing or damage resulting from errors. NHP or Terasaki reserve the right to make corrections and changes needed in subsequent edition.

Introduction

The technical data in this document relates to cascading and selectivity of TemBreak PRO with Din-T, Din-Safe and MOD6 MCBs and RCBOs. This document provides data for the following MCCB models:

- A160, A250
- P160, P250, P400, P630
- B160, B250, B400, B800, B1000, B1250, B1600
- XS2000, XS2500, XS3200
- ZS125, ZS250
- Concept Isolator (Not a TemBreak PRO product)

What is Cascading and Selectivity

Two common terminologies relating to general power back-up and system protection are: Selectivity (Discrimination) and Cascading (Back-up).

In general terms, Selectivity is used to improve system reliability and to ensure a continuous supply of power to as high a degree as possible for critical systems. Cascading on the other hand is where an upstream breaker is used to “back-up” a lower kA breaker installed downstream to clear a fault current, and is generally applied to non-critical load applications, or where economics plays a significant part in system design.

Selectivity

Selectivity, also known as ‘discrimination’, is associated with continuity of supply. The concept of selectivity is to ensure the device immediately upstream of the fault, interrupts the fault. This maintains a continuous supply to parts of the system that are fault free.

Cascading (or Back-up)

Cascading can be utilised when the potential fault that a down-stream device has to interrupt is larger than its breaking capacity. It involves the co-ordination of two devices in series being used to interrupt the fault as opposed to the downstream device alone.

The technique of cascading is used in applications where the protective devices are feeding non-essential loads.

The reason being, that in order for an upstream device to cascade with or ‘back-up’ a downstream device it may have to trip.

The technique is a recognised method for fault interruption, being stated in standards such as AS60947-2 (IEC 60947-2) for circuit breakers and AS61439 for switchboard assemblies.

Cascade/Selectivity tables

The Cascade and Selectivity tables shown in the following pages are verified according to AS/NZS 60947.

The data in these tables is to be used in conjunction with a desk study comparing the circuit break curve data. Software tools like TemCurve and PowerCAD can assist with these studies.

Cascading

ZS125, A160, P160

Cascading refers to a design verified combination of circuit breakers where, both breakers have been verified to work safely in short circuit level higher than the downstream I_{cu} ratings. Whenever there is a dash "-" this means the combination can be safely used ONLY up to the lower I_{cu} rating of both devices.

Notes
1. Downstream MCCB trip units can be TM, TF, FF, BE, BEG, SX, or SE types, unless it is specifically stated as being for one type only.

Cascading

MCCB to MCCB

Electronic Upstream

Cascading refers to a design verified combination of circuit breakers where, both breakers have been verified to work safely in short circuit level higher than the downstream I_{cu} ratings. Whenever there is a dash "-" this means the combination can be safely used **ONLY** up to the lower I_{cu} rating of both devices.

Selectivity

How Is Selectively Defined

AS/NZS 3000 defines selectivity as.

“AS/NZS 3000:2018 - 2.5.7.2.1 General

Coordination of protective devices requires consideration of both discrimination (selectivity) and backup (cascading) protection.

Discrimination (selectivity) between protective devices depends on the operating characteristics of two or more protective devices such that the protective device for the downstream circuit shall operate for a given fault current while the protective device(s) for the upstream circuit shall not operate.

Backup (cascading) depends on the characteristics of each of the two devices as well as the behaviour of the two devices when operating in series. This includes the energy let through when sharing the fault as well as the peak current withstand of the downstream device.

NOTE: Manufacturer's instructions/data should be used where available.” *

The upstream device being referred to as C1
The downstream device being referred to as C2

How Do I Ensure Selectivity

Selectivity is achieved using a discrimination study. This study can be done using ratios or manufacturer's data, depending on the rating of C2.

According to AS/NZS 3000;

“AS/NZS 3000:2018 - 2.5.7.2.3 General supply circuit discrimination (selectivity)

In accordance with Clause 2.5.7.1, to minimize loss of supply, discrimination (selectivity) shall be arranged between protective devices for outgoing circuits and the upstream protective device.

Discrimination is achieved using a discrimination study, the ratios shown below or manufacturer's data and tables. Circuit-breakers with curves shown in AS/NZS IEC 60947.2:2015 Figure K.1, current limiting and reflex tripping circuit-breakers may require special consideration.

Discrimination need not apply above the arcing fault current I_{arc} which is deemed to be in the range of 30% to 60% of the prospective short-circuit current.

Discrimination need not apply where protective devices are in series on the same circuit such as in UPS connected supplies.

Refer to Figure 2.13.

Downstream devices shall be selected to discriminate (provide selectivity) with upstream devices, using time-current curves, in accordance with the following:

- a) Circuit-breakers Two circuit-breakers, connected such that C2 is the downstream device and C1 the upstream device, shall be selected:
 - i. For ratings of C2 greater than or equal to 800 A, discrimination shall be provided by a coordination study using manufacturer's data.
NOTE: Curve references are found in AS/NZS IEC 60947.2:2015, Figure K.1.
Allowance for tolerances on settings may be required. Refer to Figure 2.14.
 - ii. For ratings of C2 greater than or equal to 250 A, and less than 800 A, discrimination shall be provided between overload curves.
Discrimination is deemed to be achieved if the overload setting of $C1 \geq 1.5 \times C2$, e.g. C1 1000 A with C2 630 A.
Refer to Figure 2.15.
 - iii. For ratings of C2 less than 250 A, discrimination is deemed to be achieved if $C1 \geq 1.5 \times C2$, e.g. C1 MCB marked C63 with MCB C2 marked C40 (i.e. both C curves). Refer to Figure 2.16
Exception: For ratings of $C2 \leq 80A$ discrimination is not required.”

NOTES:

1. ISD is not available on MCBs and only available on some MCCBs with electronic trip units.
2. Where a circuit-breaker is installed for load limiting purposes, such as on submains, reliability of supply is not required. ¹

NOTES:

1. A coordination study requires the calculation of the prospective short-circuit currents, and comparison of the operating time of various protective devices, taking into consideration the actual current seen by each protective device. Manufacturer's data should be used to assess coordination (discrimination and back up) in the short-circuit area (above the short delay or Instantaneous setting of the protective devices).
2. Detailed requirements for coordination (selectivity and back up) as well as symbols, figures and examples are given in relevant Standards as follows: MCCBs and ACBs—AS/NZS IEC 60947.2, MCBs—AS/NZS 60898.
3. If devices are to be installed above their rated short-circuit capacity, the backup protection (cascading) requirements for circuit-breaker or fuse selection needs to be determined from manufacturer's data. Discrimination (selectivity), when backup protection of a circuit-breaker is applied, is limited (partial) and the value needs to be obtained from the manufacturer.
4. Refer to Clause 2.5.5 for other requirements for $\geq 800 A$ main switchboards.
5. The electricity distributor should be consulted for discrimination requirements between installation protective devices and the electricity distributor's service protective devices. The curves and settings of service protective devices will be required. For example, a 100 A service fuse will discriminate with a 32 A MCB.
6. Discrimination requirements are not retrospective.
7. The following terms are used in Figures 2.13 to 2.18:

IPSC	=	prospective short-circuit current (see Clause 1.4.43)
I_{arc}	=	deemed maximum arcing fault current (= 60% IPSC)
t_i	=	instantaneous setting
ISD	=	short delay setting
0.01 s	=	the limit of fuse time-current.” *

*Excerpts of source material from publications such as Standards is required to study technical points completely and in full context. The direct copying of excerpts from standards publications for educational purposes is protected under moral rights by the Copyright Act of 2000.

¹ Clause 2.5.7.2.3 continues with points b, and c cover fuses to fuse and fuse to circuit breaker selectivity, and where not referenced for clarity around circuit breaker to circuit breaker requirements

Selectivity

How Do I Ensure Selectivity... Continued

“Coordination study” refers to, comparing the time-current curves of the 2 devices and ensuring that the curves do not intersect in the overload and low-level fault regions. Tools like TemCurve, PowerCad, PowerTools, and more can assist in conducting these studies.

Regarding current limiting breakers, for applications requirements going above and beyond the standards where selectivity is required in the instantaneous cross over region of the 2 curves, manufactures test data is required to complete the study, refer to the tables provided for verified combinations. For devices where C2 is less than 800A a ratio method of x1.5 can be applied.

Regarding Safety Services, **AS/NZS 3000:2018 - 2.5.7.2.2 Safety service circuit discrimination (selectivity)** outlines the requirements.

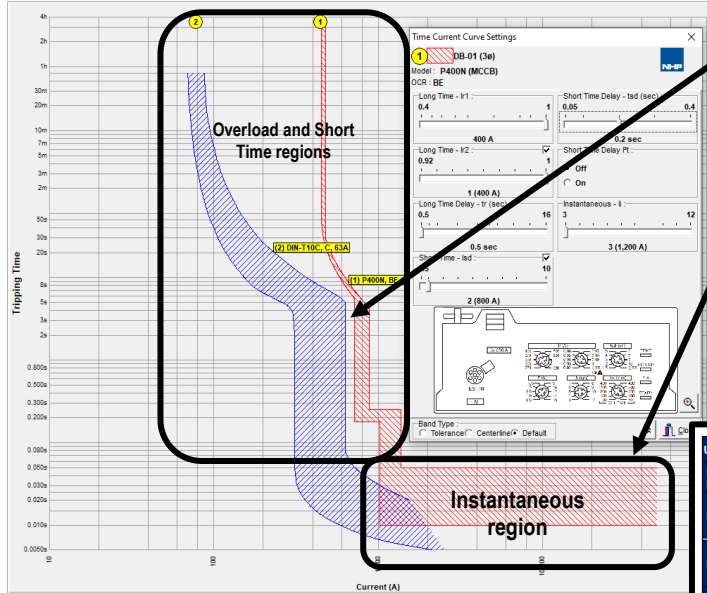

Selectivity

How Do I Use The Tables In My Study

These tables give data as to the performance of C1 and C2 where the instantaneous regions of the curves overlap.

Example 1:

C1 = P400N3400BE
C2 = DTCB10363C

As we can see the setting of the P400N allow for selectivity in the overload and short time regions, however there is a cross over in the curves in the instantaneous region. As advised before the AS/NZS 3000 does not require selectivity in the region.

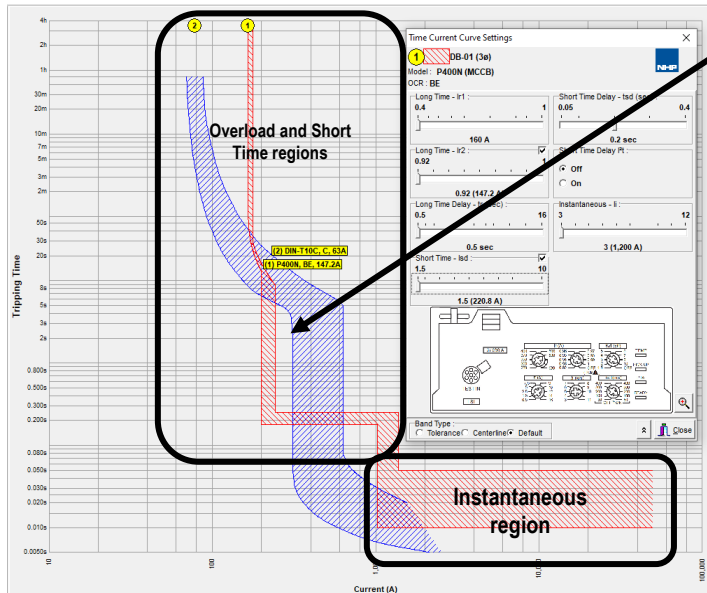

For critical applications where selectivity is needed in the instantaneous region more data is needed to be able to complete the study.

This is where the following tables give guidance as to the verified performance in these crossovers.

Upstream MCCBs		P250F, N, H	P250F	P250N	P250H	P400E	P400F	P400H	H, S
Downstream MCCB, C or D curve	kA (rms 415V)	TM	BE, SE	BE, SE	BE, SE	TM	TM, BE, SE	TM	BE, SE
DTCB8	6	15*	36	36	36	36	36	36	36
DTCB10	10	15*	36	36	36	36	36	36	36

Example 2:

C1 = P400N3400BE
C2 = DTCB10363C

In this example we have set the P400N to its minimum I_r and I_{sd} settings and we can now see that the curves are overlapping in the overload and short time regions.

Meaning even if the below tables advise selectivity in the Instantaneous region the following combination of C1 and C2 at C1's current settings do not meet the requirements for selectivity.

For more information on selectivity, it is recommended to read through the [LV Power Distribution Protection Guide](#) and consult with your local NHP representatives

Selectivity

ZS125 & A160 Thermal Magnetic

The tables below cover for thermal magnetic ZS125 & A160 MCCBs, in conjunction with thermal magnetic MCBs downstream.

The tables provide data to help with conducting selectivity studies and should be used with the study to ensure selectivity is maintained at long time and short time levels (time/current curve comparison).

Whenever there is a dash "-" selectivity is achieved up to the point of intersection of the circuit breakers time/current curves.

Values given with an asterisk (*) were achieved with the I_n setting at maximum.

Selectivity

ZS125 & A160 Thermal Magnetic

The tables below cover for thermal magnetic ZS125 & A160 MCCBs, in conjunction with thermal magnetic RCBOs downstream.

The tables provide data to help with conducting selectivity studies and should be used with the study to ensure selectivity is maintained at long time and short time levels (time/current curve comparison).

Whenever there is a dash "-" selectivity is achieved up to the point of intersection of the circuit breakers time/current curves.

Values given with an asterisk (*) were achieved with the I_n setting at maximum.

Selectivity

A250, P250, ZS250 Thermal Magnetic

The tables below cover for thermal magnetic A250, P250 and ZS250 MCCBs, in conjunction with thermal magnetic downstream MCBs. The tables provide data to help with conducting selectivity studies and should be used with the study to ensure selectivity is maintained at long time and short time levels (time/current curve comparison). Whenever there is a dash "-" selectivity is achieved up to the point of intersection of the circuit breakers time/current curves. Values given with an asterisk (*) were achieved with the I_i setting at maximum.

Selectivity

P400 Thermal Magnetic & Electronic

The tables below cover for thermal magnetic and electronic P400 MCCBs, in conjunction with thermal magnetic downstream MCBs.

The tables provide data to help with conducting selectivity studies and should be used with the study to ensure selectivity is maintained at long time and short time levels (time/current curve comparison).

Whenever there is a dash "-" selectivity is achieved up to the point of intersection of the circuit breakers time/current curves.

Selectivity

Concept Isolator

The NHP Concept Isolator is a Magnetic only MCCB (ICB). The following tables will assist with ensuring selectivity of the upstream, the concept isolator and downstream devices. The concept isolator offers no backup protection to downstream devices and requires an upstream MCCB to offer enhanced selectivity for the downstream devices.

Concept Isolator without Upstream MCCB

Whenever there the table is left blank " " selectivity is not possible.

Whenever there is a dash "-" selectivity is achieved up to the point of intersection of the circuit breakers time/current curves.

Selectivity

Concept Isolator

The NHP Concept Isolator is a Magnetic only MCCB (ICB). The following tables will assist with ensuring selectivity of the upstream, the concept isolator and downstream devices. The concept isolator offers no backup protection to downstream devices and requires an upstream MCCB to offer enhanced selectivity for the downstream devices.

Concept Isolator with Upstream A160 or P160_TM

Whenever there the table is left blank " " selectivity is not possible.

Whenever there is a dash "-" selectivity is achieved up to the point of intersection of the circuit breakers time/current curves.

Selectivity

Concept Isolator

The NHP Concept Isolator is a Magnetic only MCCB (ICB). The following tables will assist with ensuring selectivity of the upstream, the concept isolator and downstream devices. The concept isolator offers no backup protection to downstream devices and requires an upstream MCCB to offer enhanced selectivity for the downstream devices.

Concept Isolator with Upstream P250 Electronic

Whenever there the table is left blank " " selectivity is not possible.

Whenever there is a dash "-" selectivity is achieved up to the point of intersection of the circuit breakers time/current curves.

Selectivity

Concept Isolator

The NHP Concept Isolator is a Magnetic only MCCB (ICB). The following tables will assist with ensuring selectivity of the upstream, the concept isolator and downstream devices. The concept isolator offers no backup protection to downstream devices and requires an upstream MCCB to offer enhanced selectivity for the downstream devices.

Concept Isolator with Upstream E250, S250, H250, & L250

Whenever there the table is left blank " " selectivity is not possible.

Whenever there is a dash "-" selectivity is achieved up to the point of intersection of the circuit breakers time/current curves.

- Notes
- Downstream MCCB trip units can be TM, TF, FF, BE, BEG, SX, or SE types, unless it is specifically stated as being for one type only.
 - Upstream MCCB trip unit are to be electronic, BE, BEG, SX or SE type

Selectivity

ACBs

All Terasaki ACB are non-current limiting short-circuit protection devices, depending on the trip unit to identify the tripping time and thus discrimination can be ensured by desk study alone, in accordance with AS/NZS IEC 60947-2 Annex A.

By ensuring that the protection curves of the upstream are not overlapping with the downstream (utilising the settings of the current and time delays in the trip unit of the upstream and downstream) that will help to secure the selectivity between the ACB's and MCCB's.

Notice:

If the following requirements are met the selectivity figures for AR ACBs with TemBreak PRO MCCBs are as follows in the tables below.

- The Upstream ACBs are to have I_i (instantaneous) set to NON, and the MCR (make current release) set to ON.
- Time/Current curves do not overlap
